Search For Equal  
Elements

- $k$ -Distinctness: Given a string

$$x = (x_1, \dots, x_n)$$

find  $k$  elements that are equal.

- Case  $k = 2$  is known as **Element Distinctness**.
- Inspired a number of techniques in upper and lower bounds.

Phase Kickback

Non-Uniform  
Distribution

Search For Equal  
Elements

## Proposition

The input oracle  $O$  in the Fourier basis acts as

$$O: |\hat{\sigma}\rangle_{\mathcal{X}}|i\rangle_{\mathcal{I}}|c\rangle_{\mathcal{C}} \mapsto |\overline{\sigma + \{i \mapsto c\}}\rangle_{\mathcal{X}}|i\rangle_{\mathcal{I}}|c\rangle_{\mathcal{C}}.$$

where  $\{i \mapsto c\} \in \mathbb{Z}_q^n$  is a function

$$j \mapsto \begin{cases} c, & \text{if } j = i; \\ 0, & \text{otherwise;} \end{cases}$$

and addition of function is performed element-wise.

Problem

Pillars

Quantum Query  
Algorithm

Algorithm Combined

Phase Kickback

Non-Uniform  
Distribution

Search For Equal  
Elements

## Proposition

The input oracle  $O$  in the Fourier basis acts as

$$O: |\hat{\sigma}\rangle_{\mathcal{X}}|i\rangle_{\mathcal{I}}|c\rangle_{\mathcal{C}} \mapsto |\overline{\sigma + \{i \mapsto c\}}\rangle_{\mathcal{X}}|i\rangle_{\mathcal{I}}|c\rangle_{\mathcal{C}}.$$

- Oracle acts in  $\mathcal{X}$ , not in  $\mathcal{A}$ , which we have much more control over.
- Gives important piece of intuition: the state  $|\hat{\sigma}\rangle_{\mathcal{X}}$ 
  - has knowledge about the variables in the support of  $\sigma$ ;
  - has no knowledge about the variable outside of it.

Problem

Pillars

Quantum Query  
Algorithm

Algorithm Combined  
with Input

Phase Kickback

Non-Uniform  
Distribution

Search For Equal  
Elements

## Proposition

The input oracle  $O$  in the Fourier basis acts as

$$O: |\hat{\sigma}\rangle_{\mathcal{X}} |i\rangle_{\mathcal{I}} |c\rangle_{\mathcal{C}} \mapsto |\overline{\sigma + \{i \mapsto c\}}\rangle_{\mathcal{X}} |i\rangle_{\mathcal{I}} |c\rangle_{\mathcal{C}}.$$

## Corollary

After  $t$  queries, the uniform state of the algorithm

$$\psi_t, \psi'_t \in \mathcal{X}_{\leq t} \otimes \mathcal{A},$$

where  $\mathcal{X}_{\leq t}$  is spanned by  $|\hat{\sigma}\rangle_{\mathcal{X}}$  with support size  $\leq t$ .

- The algorithm knows values of some  $\leq t$  variables.

# Search For Equal Elements

Problem

Pillars

Non-Uniform  
Distribution

Search For Equal  
Elements

Formulation

Anti-Concentration

Is given by a set  $M$  of partitions  $\mu$  of  $[n]$ .

- Recall that partitions  $\mu \in M$  of  $[n]$  are related to inputs  $y \in \mathbb{Z}_q^n$  by  $i, j$  share a block of  $\mu$  iff  $y_i = y_j$ .
- We **relax** this condition and consider  $Y_\mu = \mathbb{Z}_q^\mu$ .
- If  $q \gg n^2$ , there is not much difference between the strict and the relaxed versions.

**Advantages:**

- We can introduce Fourier basis  $|\mu, \hat{\tau}\rangle_{\mathcal{Y}}$  with  $\tau \in \mathbb{Z}_q^\mu$  in  $\mathcal{Y}$ .
- The transfer operator has a very nice form:

$$\Upsilon_\mu: |\hat{\sigma}\rangle_{\mathcal{X}} \mapsto |\mu, \hat{\tau}\rangle_{\mathcal{Y}} \quad \text{with} \quad \tau(B) = \sum_{i \in B} \sigma(i) \quad \text{for all } B \in \mu.$$
